Comparison of DIII-D Experimental Ion Temperature Gradients with the Critical Gradient as Calculated by the GKS Code

D.R. BAKER, G.M. STAEBLER, General Atomics — The ion thermal diffusivities ($\chi_i$) in DIII-D discharges exhibit a strong nonlinear dependence on the measured temperature gradients. This nonlinear dependence has the appearance of a critical gradient in the sense that when the temperature gradient is less than a certain value $\chi_i$ is small and when it reaches or surpasses this value then $\chi_i$ increases rapidly. Here we present a comparison between the measured ion temperature gradients and the “critical” gradient as calculated by the GKS code. The existence of a “critical” gradient can depend on whether the electrons are treated adiabatically or kinetically. It also depends on the relative size of the density gradient. For large density gradients the transport due to trapped electron modes can produce transport even when the ion temperature gradient mode is stable. This could eliminate the effect of a critical gradient. We will compare the incremental ion thermal diffusivity deduced from the experimental data with the predictions of gyrofluid and gyrokinetic ITG turbulence simulations.
