Tritium Recovery From Carbon Co-deposits: ex situ Studies in Preparation for an in situ Thermal Oxidation Experiment in DIII-D* C. Tsui, J.W. Davis, A.A. Haasz, B.W.N. Fitzpatrick, A.G. McLean, P.C. Stangeby, Y. Mu, U. Toronto; S.L. Allen, LLNL; W.P. West, P.L. Taylor, K.L. Holtrop, A.W. Hyatt, R.L. Boivin, GA; K. Umstadter, UCSD – Tritium trapping in carbon co-deposits is potentially a major cause of T retention in ITER. A possible solution is “thermo-oxidation,” involving sub-atmospheric molecular O\(_2\) at 250°-350°C. Ex situ lab tests (at U. Toronto) of graphite tiles removed from DIII-D have demonstrated the method in principle and generated a comprehensive database on removal rates. Ex situ tests were also performed for special components (e.g., diagnostic mirrors) used in DIII-D to assess potential damage. The next step is in situ demonstration in DIII-D to show that the D (as proxy for T) and C removed from the tiles actually leaves the vessel, that vessel components are not damaged, and that plasma operation can be recovered quickly. Lab results and implications for the in situ test are discussed.
