Long-Wavelength Turbulence Scaling Properties in DIII-D,*
G.R. McKee, D.J. Schlossberg, M.W. Shafer (UW-Madison), C.H. Holland (UCSD), P. Gohil (GA) – The scaling properties of long-wavelength density fluctuations are investigated in DIII-D L-mode and H-mode plasmas utilizing the expanded high-sensitivity 2D Beam Emission Spectroscopy (BES) system. BES employs a 64-channel system that utilizes a radially-scannable 8x8 array sampling multiple radial and poloidal correlation lengths, allowing for full sampling of the 2D wavenumber spectrum. Measurements of turbulence as a function of several important dimensionless parameters ($\kappa, T_\text{e}/T_\text{i}$, ion mass, $\rho_*$) are obtained, showing that fluctuation intensity increases strongly with decreasing plasma elongation (at constant $q$), consistent with increased thermal transport and reduced energy confinement. In contrast, increasing $T_\text{e}/T_\text{i}$ increases momentum and thermal transport with little change in low-$k$ density fluctuations. Measurements obtained during a $\rho_*$ ($\rho_*/a$) scan in hydrogen will also be presented. Together, these measurements will be crucial for comparing with transport simulations, such as GYRO and TGLF.
