Impact of Divertor Magnetic Balance and Particle Drifts on Radiating Divertor Behavior in DIII-D,* T.W. Petrie, N.H. Brooks, J.R. Ferron, A.W. Hyatt, A.W. Leonard, T.C. Luce, M.R. Wade, W.P. West, GA, M.E. Fenstermacher, M. Groth, C.J. Lasnier, G.D. Porter, LLNL, J.G. Watkins, SNL – Recent DIII-D experiments show that both magnetic balance between upper and lower divertors and the particle drifts in the SOL and divertors are important to understanding how argon impurities accumulate in double-null plasmas in a “puff and pump” radiating divertor scenario. The best results to-date in terms of coupling a radiating divertor approach to an H-mode plasma with minimal degradation in $\tau_E$ have been produced in a double-null shape biased opposite to the ion $B \times \nabla B$ drift direction. Edge transport modeling with UEDGE [1] shows that the maintenance of low core impurity levels in this configuration can be largely ascribed to the central role of particle drifts. Additionally, it is found that ion $B \times \nabla B$ drift direction plays a much more important role than divertor closure in controlling plasma density.
