November 2–6, 2009, Atlanta, Georgia**

Neutral Fueling From Recycling and Contributions to Pedestal Density Profiles in DIII-D,* A.W. Leonard, R.J. Groebner *GA*; G.D. Porter, *LLNL* — Pedestal density widths in DIII-D are compared with the ionization profiles due to recycled neutrals. The neutral ionization profile is determined by neutral Monte-Carlo calculations based on ion flux measurements to the divertor and a plasma background reconstruction constrained by measurements. Previous studies have indicated that pedestal ionization is dominated by the inboard divertor neutral sources with smaller contributions from the main chamber in DIII-D. A density scan in H-mode is examined where the pedestal density width remains constant. The pedestal ionization rate increases at high density and inboard divertor detachment due to a longer mean free path for neutrals and an increased recombination source for neutrals. The possibility of an inward plasma pinch is explored as a possible explanation for the nearly constant pedestal density width under changing conditions of neutral sources and divertor plasma parameters.
