Presented at  
Twenty-third IAEA Fusion Energy Conference  
Daejeon, Republic of Korea

October 11-16, 2010

# Overview

- **Introduction**
- **Massive particle injection**
  - Massive Gas Injection (MGI)
  - Shattered Pellet Injection (SPI)
  - Shell Pellet Injection (SHPI)
- **Active feedback control**
- **Magnetic deconfinement of runaway electrons**
- **Conclusion**

# The Danger of Runaway Electrons on ITER

- ITER is very likely to generate high runaway electrons (RE) currents due to its high plasma current (15 MA). Avalanche multiplication Gain on ITER is  $10^{20-30}$  vs 100 on DIII-D

$$I_{RE} \approx I_{seed} \exp \left( \frac{I_P}{V_A \ln \Lambda} \right) \text{ with } I_A \approx 0.02 \text{ MA}$$

- These high energy RE beam can damage the plasma facing components

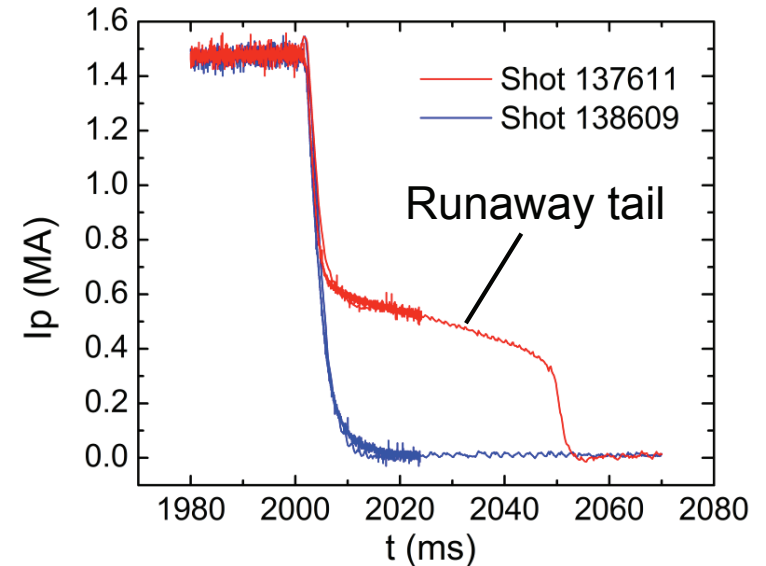

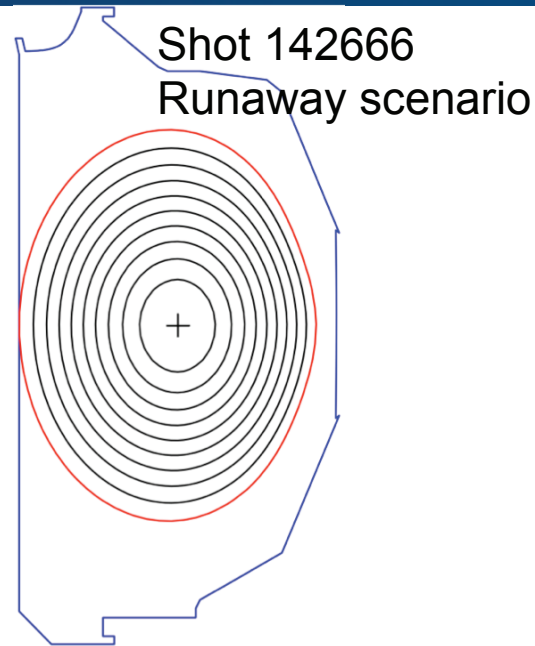

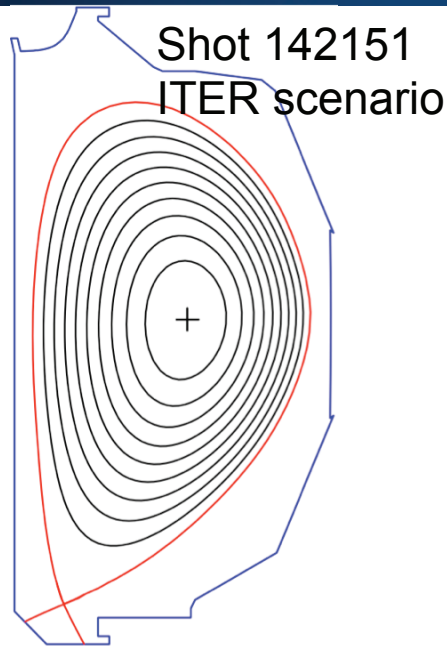

(from F. Saint-Laurent, EPS 2009)

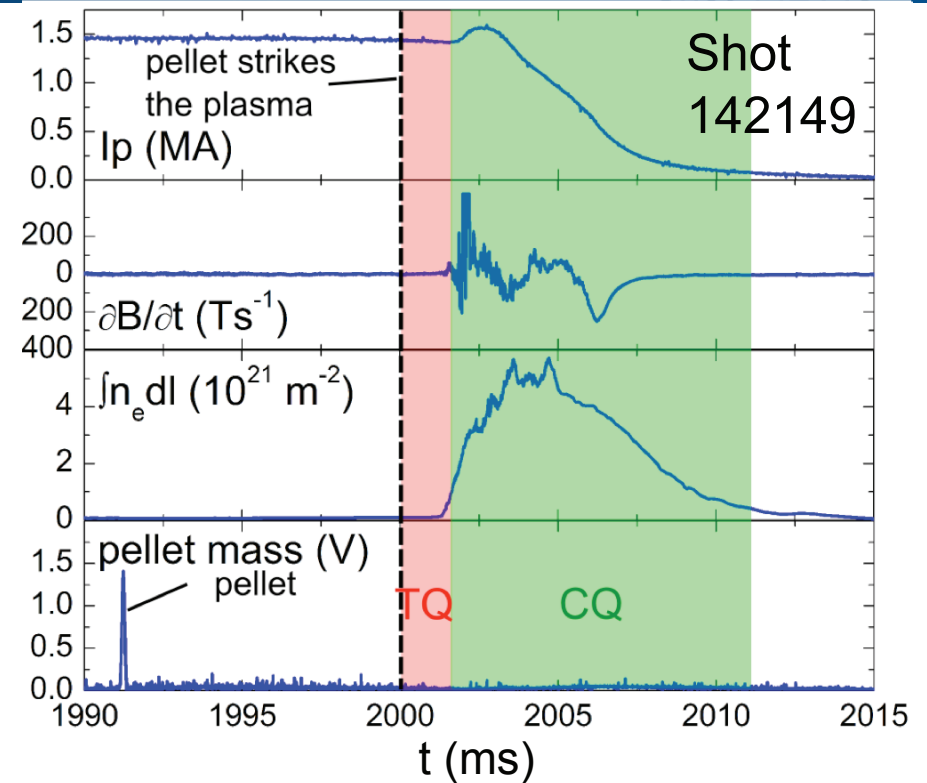

(courtesy of G. Martin)

# Plasma Scenarios Used During these Experiments

- 2 scenarios were used during the RE mitigation experiments
- The ITER relevant scenario: diverted elongated H mode NBI heated. Massive particle injection applied to terminate the discharge
- Discovery that low elongation limited can produce reliably significant runaway electrons (10x higher reliability than diverted elongated): used to test mitigation techniques on an existing RE beam

# Reaching the Rosenbluth Density

- The massive particle injection goal is to increase the density where the runaways are generated and the Rosenbluth density
- This would prevent the avalanche multiplication process expected to be the main runaway generation mechanism in ITER

# The MGI Valve on DIII-D: MEDUSA

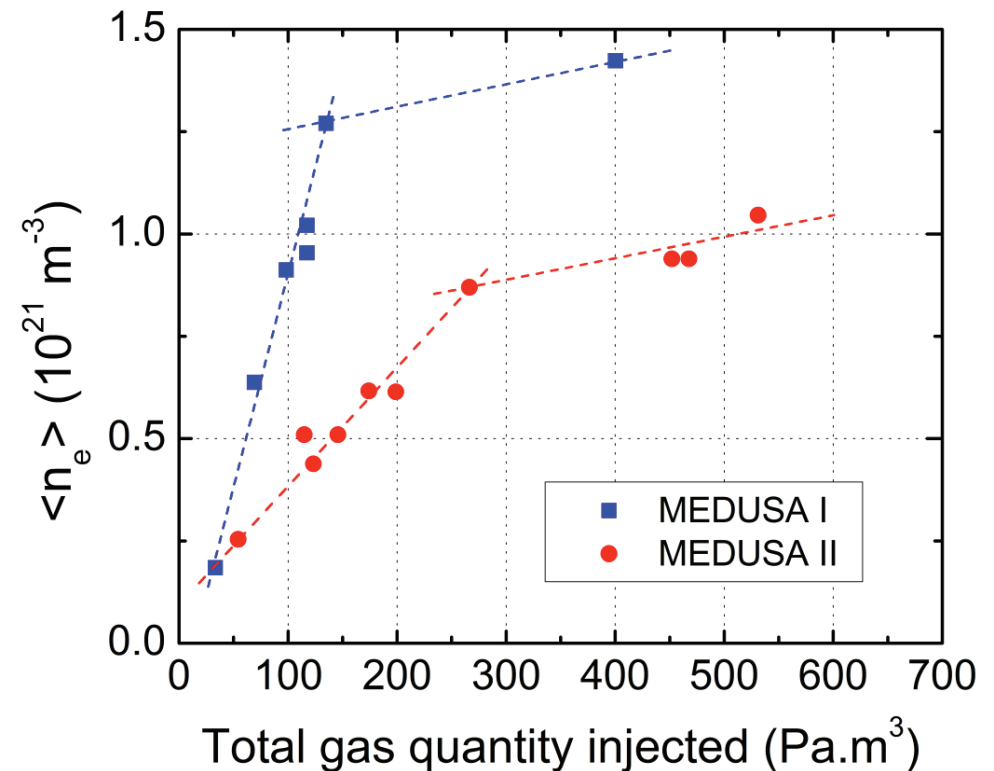

- The MEDUSA valve: array of 6 “small” fast valves (can be actuated faster than one “big valve”)
- Can inject up to  $400 \text{ Pa}\cdot\text{m}^3$  in 1 ms (vs  $\sim 10$  ms for one “big” valve)
- Can dial separately quantity injected and pulse duration

# A Direct Duct is Critical for the Efficiency of MGI

- Significant change in the configuration of the MEDUSA duct slowing down the gas flow
- This modification dropped the assimilation efficiency of the MGI system by ~50%
- The flow rate has a major impact of the assimilation efficiency

# The Pulse Duration has an Important Effect on the Assimilation Efficiency of MGI

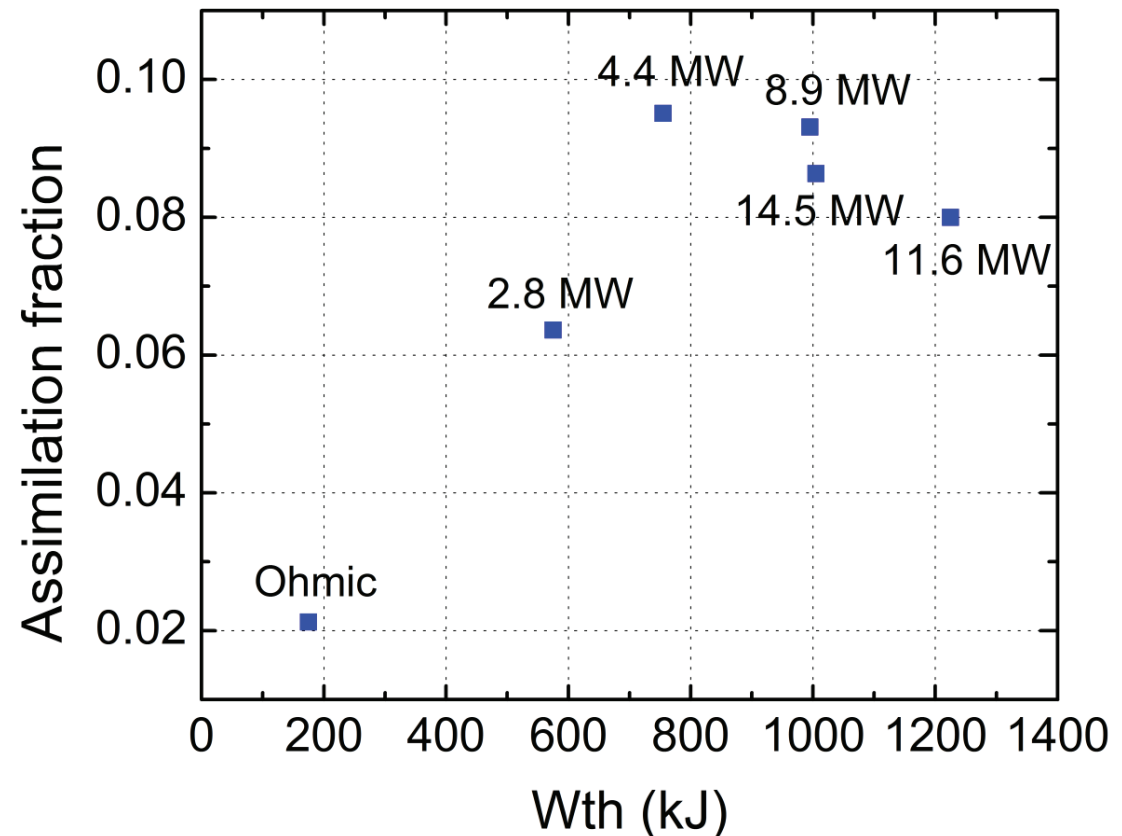

- The MEDUSA array allowed to study the assimilation efficiency as a function of the injected quantity of helium gas using 2 methods
  - Varying the gas pulse duration
  - Varying the number of valves actuated
- A limit observed only on the pulse duration (~1.5-2 ms)
- Correlated with the end of the TQ – only particles injected before TQ ends assimilated ?

# The Thermal Energy Content as a Rather Limited Effect on the Assimilation Efficiency for MGI

- Scan the thermal energy content (180-1220 kJ) by varying the NBI injected power (0-14.5 MW)
- A positive dependence is observed but only at low energy content (<800 kJ). Above this value, the assimilation efficiency saturates at ~9%

# Principle of the SPI

- A cryogenic pneumatic pellet injector shooting big pellets (~15 mm x 20 mm cylinders)
- The pellets are shattered before entering the plasma by bouncing on 2 plates
- The small shards are no danger for the PFCs and increase the surface area for more

# Better and Faster Assimilation for the SPI in Similar Conditions Due to the Deeper Penetration

- The density after transport and homogenization is 2 times higher for the SPI (same amount injected:  $\sim 400 \text{ Pa}\cdot\text{m}^3$ )
- Fast visible camera shows SPI cloud penetrating deeper than MGI
- The maximum density is reached earlier in the CQ: on DIII-D the RE flattop is already existing at that stage

# Weak Dependence of the Assimilation with the Thermal Energy of the Plasma for the SPI

- The assimilation efficiency increases with the thermal energy content of the plasma
- The ohmic shot allows a higher assimilation efficiency: longer TQ ?
- Ionization limit reached ?

# Total Number of Electrons During a SPI Fast Shutdown Varies Significantly

- Using the different local density measurements to get the total number of electrons  $N_{\text{tot}}$
- After an initial decrease of  $N_{\text{tot}}$  during the TQ. Increases again at the beginning of the CQ
- Possible explanations
  - Heat transport
  - Wall recycling

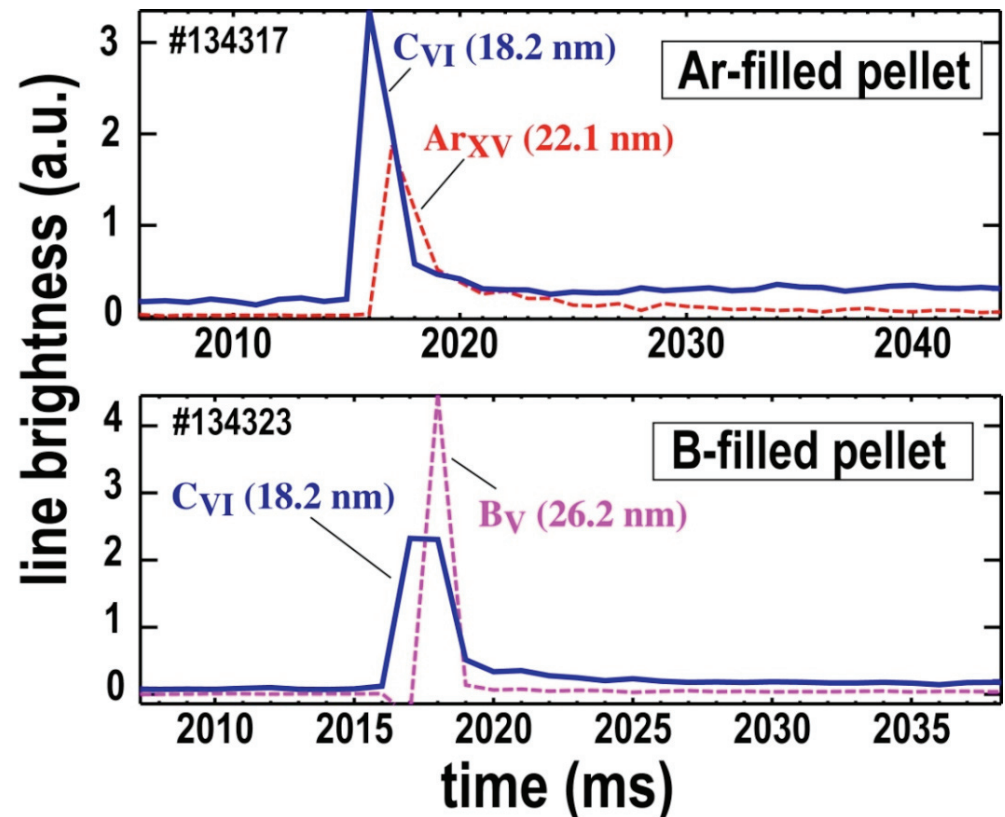

# The SHPI Concept

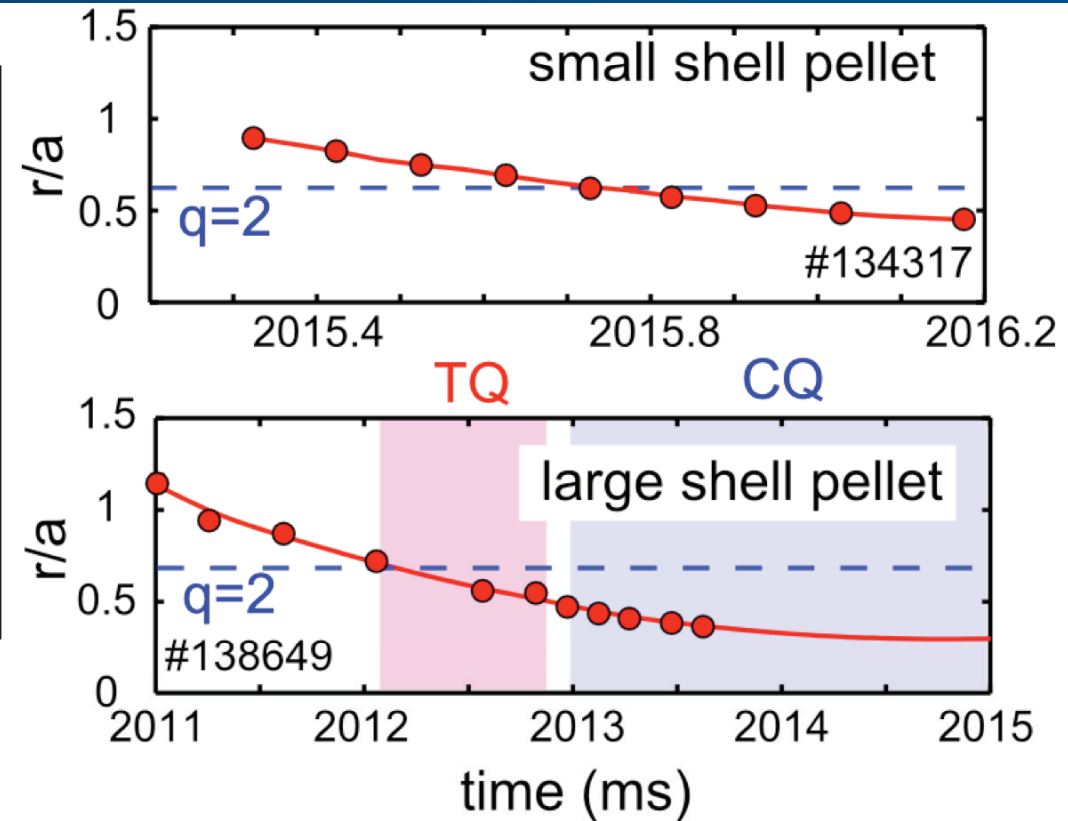

- Would like to achieve core total electron densities  $n_{\text{tot}} \sim 4 \times 10^{16} / \text{cm}^3$  in DIII-D to demonstrate total collisional suppression of runaway electrons deep in the core
- Requires of order 1 g  $\sim 1 \text{ cm}^3$  of material deposited in core of DIII-D
- First large shell pellet experiments were attempted in 2009 using  $D = 1 \text{ cm}$ ,  $t = 0.4 \text{ mm}$  polystyrene shells filled with boron powder

# Successful Proof of Principle of the SHPI Using Small 2 mm Shells

- Fast camera data show the small shell penetrating deep in the plasma and releasing its payload (boron powder or argon gas)
- UV spectrometer shows carbon spike from polystyrene shell
- Then highly-charged argon or boron ion spike, consistent with payload release into plasma
- No fast shutdown triggered: the amount of particles in the payload is too small

# The Large Shell Pellet Triggers a TQ when Reaching $q=2$ (SHPI)

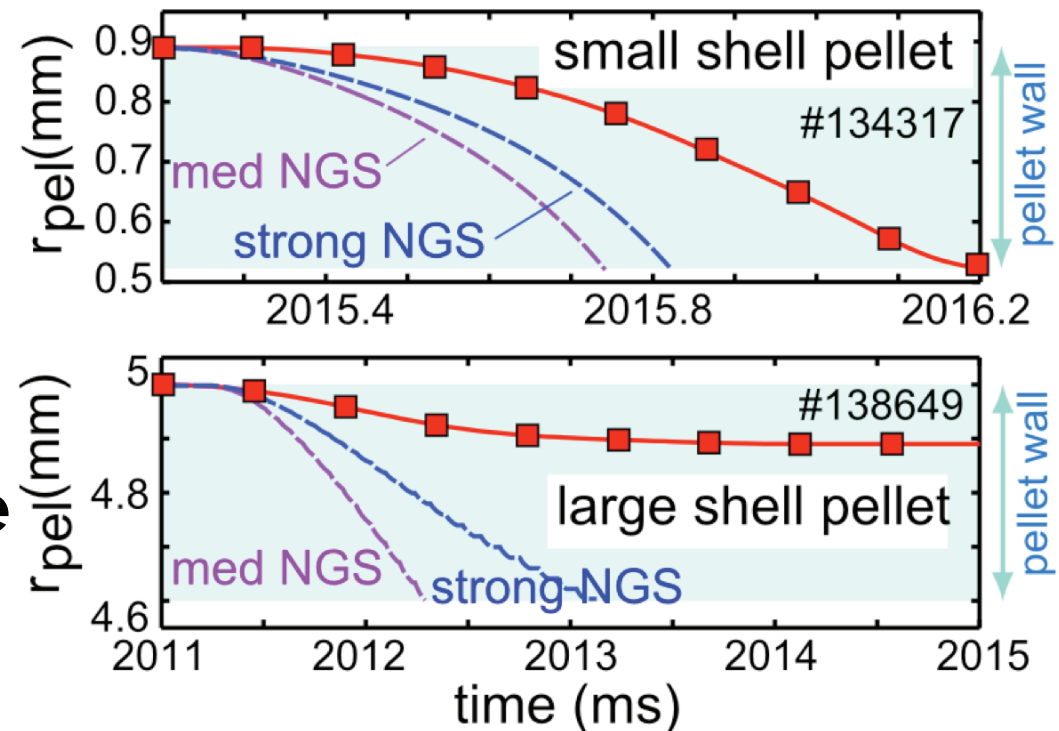

- The large shell pellet did trigger a disruption
- The TQ is initiated when the pellet reaches  $q=2$
- Strong local cooling on  $q=2$  initiate major instabilities
- No indication that the payload has been released

# The Big Shell did not Burn all the Way Through (SHPI)

- The modeling using a modified version of NGS (Neutral Gas Shielding) theory applied to polystyrene predicts breakoff at the center
- The measured ablation rate at least 50% lower than expected : pre-cooling effect ?

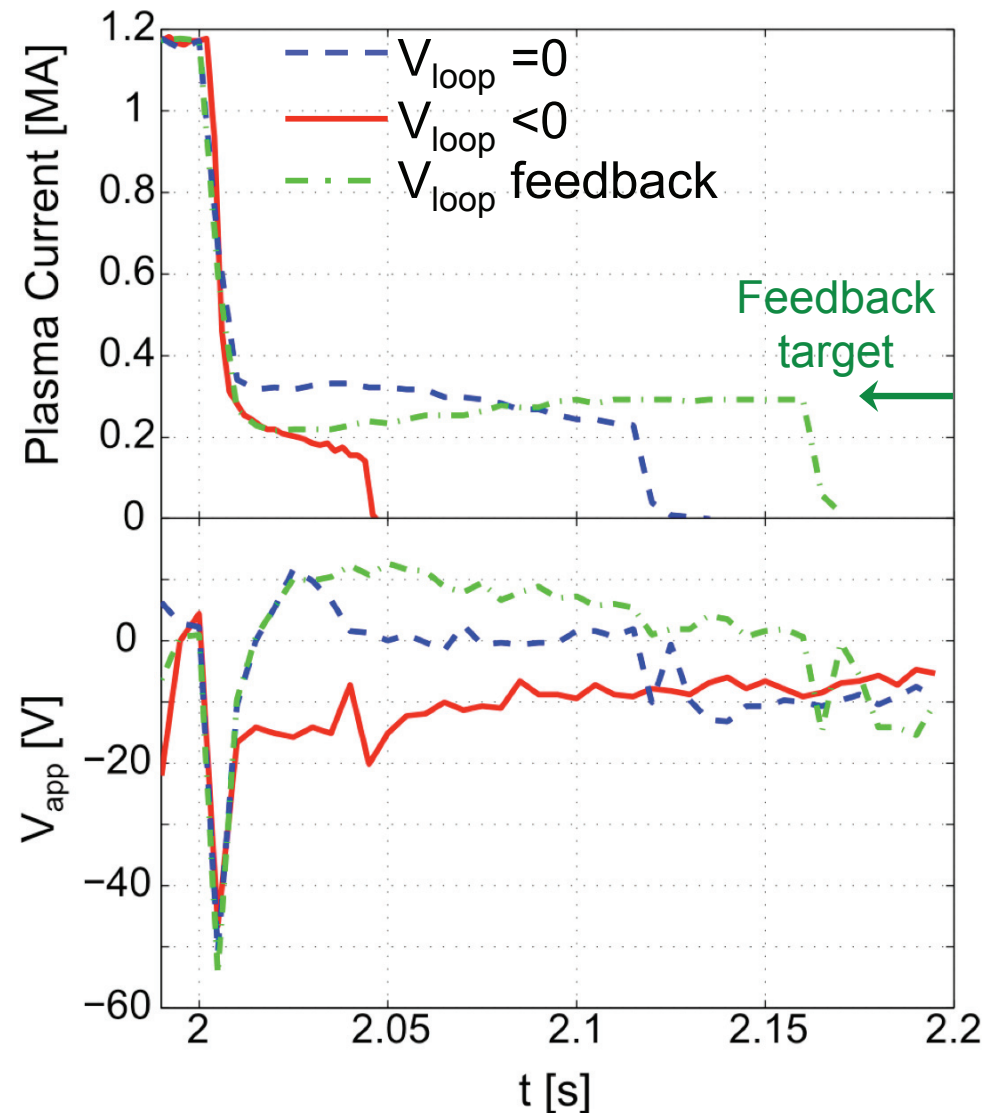

# Position Feedback Control of the RE Channel Achieved

- **Vertical position controlled**
  - Rather low performance
  - Response to an arbitrary target
- **Radial position control still needs improvement**
  - Requires HFS and LFS control coils
  - Results in an elongated separatrix: risk of VDE ?
  - Achievement of diverted separatrix: no direct contact with the wall
- **Duration of the RE beam still limited by fast instabilities**
  - Sudden loss of the RE beam always observed (kink ?)
  - Loss of vertical position control because of elongation (VDE ?)

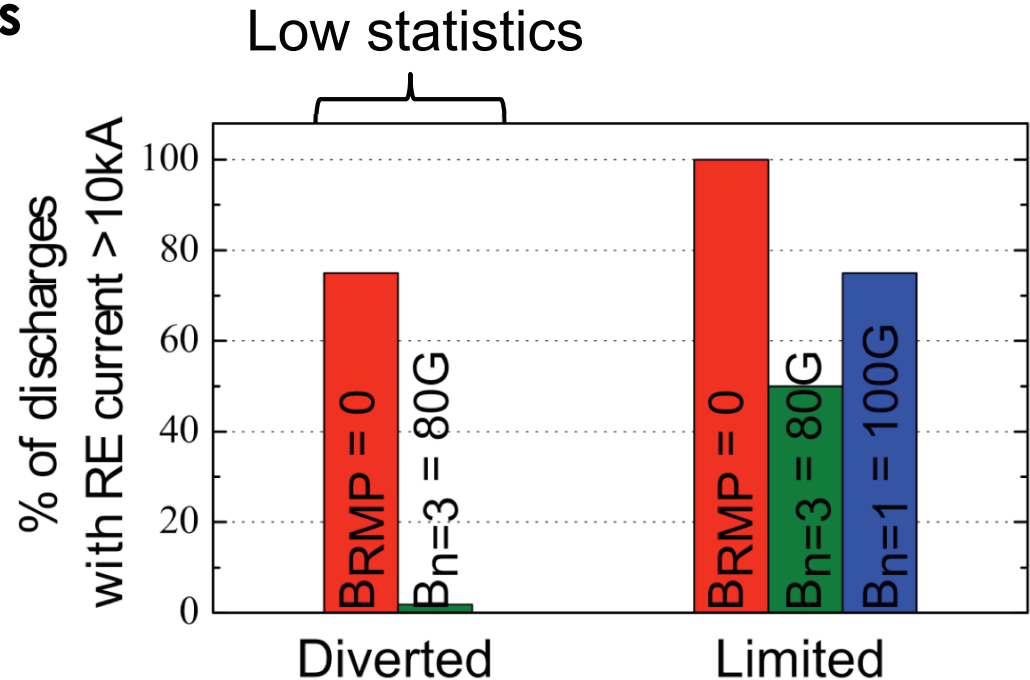

# Control of the RE Current Amplitude Achieved

- **Comparison shots with different external loop voltage  $V_{app}$  applied**
  - $V_{app} < 0$  lowers the RE current
  - $V_{app} = 0$  induces a slow “natural” decay
  - $V_{app} > 0$  increases the RE current
- **Demonstration of RE current feedback control using the central solenoid**
- **But the beam is systematically lost during a final fast event (VDE, kink ... ?)**

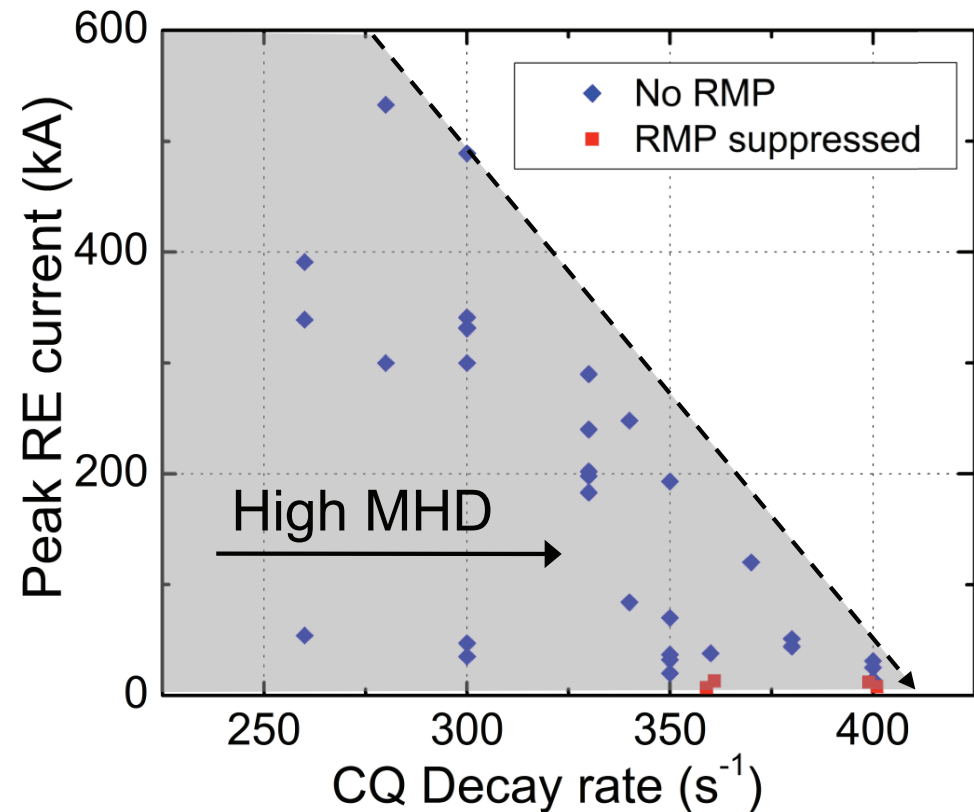

# Applying a Non-axisymmetric Field Appears to Suppress the Runaways

- Experiments achieved to test the effect of  $n=3$  and  $n=1$  fields (19 shots) applied with internal coils
  - Field applied on the existing beam
  - Field applied during the TQ (before the beam appears)
- The probability of getting a runaway beam drops by 50%
- No observable effect on an existing beam: the RMP field would affect the seed population before the avalanche process can take place

# Link Between the Initial Runaway Seed and the MHD Activity During the TQ?

- Correlation observed between the peak runaway current and the initial  $I_p$  decay rate
- $I_p$  decay rate characterize the TQ MHD activity:
  - MHD amplitudes determines the convected heat flux to the wall during the TQ
  - Induces also the deconfinement of the initial runaway seed: lower seed would result in lower final runaway current
- The RMP would increase the initial MHD activity, which would explain the mitigation observed

# Conclusion

- The new SPI technique shows promising results: good penetration and assimilation
- The parameters scan showed that the initial flow rate of MGI is critical for its efficiency
- The SHPI technique requires fine tuning to be efficient
- The runaways control technique appears efficient and provides an opportunity to apply other mitigation techniques on an existing runaway beam
- The RMP showed some efficiency in mitigating the initial runaway seed but requires further studies to improve its efficiency
